Abstract

Home-grown protein crops as an alternative to soya in dairy cattle meals, as well as other sustainable ethical-based practices, have been proposed to increase the sustainability of dairy production. Data on consumer acceptance of the three novel sustainable production strategies of 'agroforestry', 'prolonged maternal feeding' of young cattle and 'alternative protein source' were collected through an online survey on consumer in six European Union countries: Austria, Belgium, Denmark, Finland, Italy and the UK. Using Chen's extended version of the Theory of Planned Behaviour model, the underlying model hypotheses on the attitudes and intentions of these consumers towards these production practices were tested, to establish the explanatory power of the model in the specific context of novel sustainable production strategies. Furthermore, the influence of gender and consumer ethical choices on their attitudes towards these innovative practices was also tested. These data show that 'prolonged maternal feeding' is the novel production practice that has the highest level of acceptance by consumers in all of these countries, with the least accepted practice as 'alternative protein source'. Unexpectedly, increased availability of home-grown feed, which is grounded on both farmer and societal interests for higher input self-sufficiency and more sustainable production practices, was little appreciated by consumers, although their intentions appear to be dependent on their moral norms.

Keywords: Sustainable dairy farming, Animal welfare, Alternative feed, Organic and low-input farming, Consumer acceptance

Introduction

Innovation in an increasingly globalised dairy market is an essential strategic tool for the dairy industry to achieve a competitive advantage (Jordana 2000; Bishop 2006; Kühne et al. 2010; Almlí et al. 2011). However, not all innovation impacts upon consumers in the same way. Product innovation, such as new products or new packaging, are more easily noticed by consumers than, for example, process and system innovations, which are more difficult for the consumer to understand unless they are embedded in specific quality cues (Grunert 2005). Also, innovation in traditional sectors like dairy farming can be a cause of cognitive dissonance, because consumers tend to reject

innovations that can be perceived as altering the authenticity of traditional foods (Almli et al. 2011).

Previous studies have shown that consumers tend to accept processing-technology innovations on the condition that they do not modify the intrinsic attributes of the product (Guerrero et al. 2009). Most studies have investigated the introduction of product innovation (e.g. packaging, labelling, ingredients; Luce et al. 2000; Onwezen and Bartels 2011; Vanhonacker et al. 2013), while fewer studies have concentrated on process innovations, the most 'popular' of which are genetic modifications and nano-technologies (Grunert et al. 2001; Verdurme et al. 2003; Anderson et al. 2006; Sodano et al. 2016), along with organic food (Napolitano et al. 2010a, b; Bjorklund et al. 2014).

The goal of the present study was to examine consumer perceptions of selected innovations in organic and low-input dairy systems. This study forms part of a larger European-funded project that is aimed at enhancing the competitiveness and environmental sustainability of these systems. Among process innovations, we focus here on 'grassroots innovations'. These are defined as 'novel, bottom-up solutions for sustainable development', brought forward by a network of activists and organisations (Hermans et al. 2016). Among these sustainable strategies and solutions, sustainable intensification and agroecology in ruminant farming systems have been proposed as ecologically benign, socially fair and economically viable (Dumont et al. 2018). Similarly, organic and low-input dairy farming has been shown to reduce environmental harm by reducing external input use (Scollan et al. 2017). In general, strategies involving sustainable farming practices have been proposed as process innovations to reduce the impact of dairy farming on the environment and to increase animal welfare and social acceptance of the dairy sector (Padel et al. 2015).

Building on innovations identified in earlier studies of consumer acceptance of farm-level innovations and innovative practices of dairy farmers (Nicholas et al. 2014; Mandolesi et al. 2015), the present study thus explored consumer preferences towards selected novel sustainable farm-level practices in the dairy supply chain. These innovative practices were designed to address wider issues of sustainability of dairy farming, and they were focused on the following:

- Feeding of ruminants with forage-based diets and home-grown feeds
- Animal management for health and welfare

Specifically, the following three practices were selected after extensive qualitative preliminary research and analysis of stakeholder involvement (Nicholas et al. 2014; Mandolesi et al. 2015). They represent potential solutions to increase the competitiveness and sustainability of the organic and low-input dairy farming supply chain:

- *Agroforestry*. Integration of animals (i.e. cows, sheep) and trees on the same plot of land
- *Prolonged maternal feeding*. Calves and lambs are allowed to suckle directly from their mothers (or a foster mother) for the first 3–5 months after they are born.
- *Alternative protein source*. Use of home-grown protein crops, such as lupins, beans and peas, as animal feed.

Theoretical framework and hypotheses

In the relevant literature, all of the proposed models that deal with the acceptance of innovations by consumers derive from the Theory of Planned Behaviour (TPB), as proposed by Ajzen (1991). TPB proposes four predictors:

- ‘Intention to behaviour’, which has a direct impact on a specific behaviour, and which in turn is inferred by personal attitude, subjective norms and perceived behavioural control
- ‘Attitude towards behaviour’, the attitude that an individual has to adopt or not adopt a specific behaviour
- ‘Subjective norm’, the influence that the view of others has on an individual’s choices
- ‘Perceived behavioural control’, factors that might facilitate or constrain the performance of the behaviour

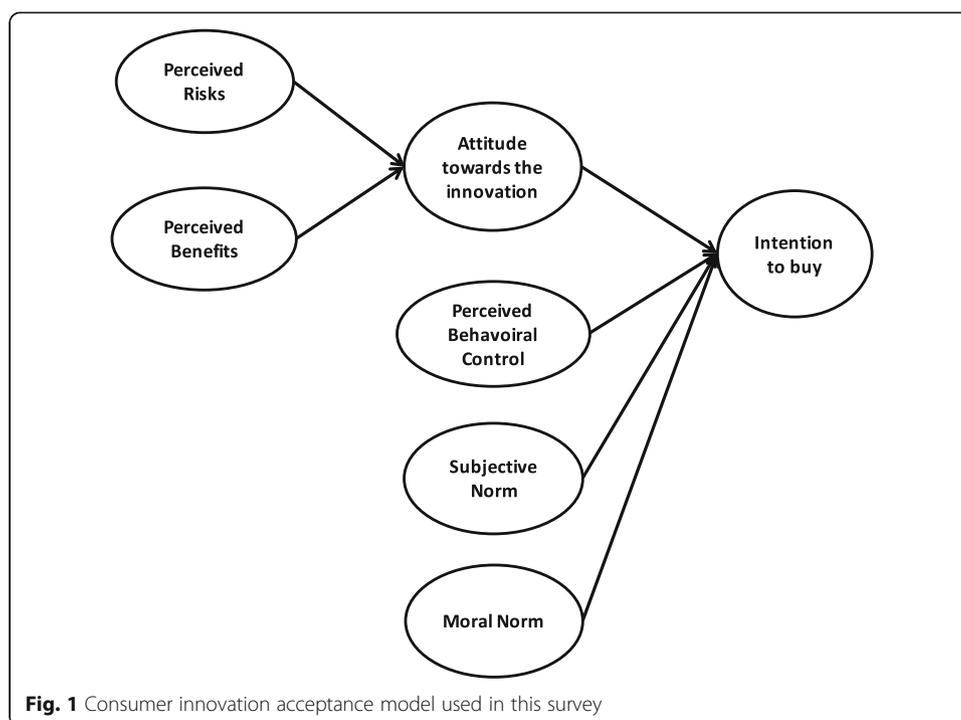

In the food sector, the model has been applied often to the acceptance of controversial food production technologies, such as genetic modification. Bredahl (2001) extended the TPB model to food, particularly with regards to attitude formation. A simplified version of the model was proposed and tested by Chen (2008). ‘Attitude towards behaviour’ has further antecedents in ‘attitude to food produced by the alternative technology’ (Chen 2008) and ‘attitude towards the technology used in food production’ (Bredahl 2001). The present model used the Bredahl construct in the specification of the structural model. This attitude is further measured by the ‘perceived risks/benefits’ of the new technology.

This theoretical model has been used in numerous studies that have investigated the acceptance of innovation among consumers. This vast empirical literature has focussed on the acceptance of, e.g. organic, fair trade, functional or genetically modified food (e.g. Bredahl 2001; Ozcaglar-toulouse et al. 2006; Vermeir and Verbeke 2007; Arvola et al. 2008; Mazzocchi et al. 2008; O’Connor and White 2010). Of note, in contrast to farmers—who can actually decide to adopt or not to adopt one or more of these innovations—consumers can only express their attitudes as to whether the farmers are using or not using these innovations.

The modifications to the original TPB model used in this study are now described (Fig. 1).

Given the importance of the values that motivate consumers towards the purchase of organic and other ‘green’ food products (Zanoli and Naspetti 2002; Arvola et al. 2008; Zhu et al. 2013), we modified the Bredahl and Chen extended TPB models and included a further construct: the moral norm (Bredahl 2001; Dean et al. 2008). The core of the adapted model remains with the two variables: attitude and intention. Attitude towards adopting an innovation practice was further measured by two antecedents: risks and benefits. The two ‘norms’ variables (the influence of ‘significant others’ expressed by the variable subjective norm, and the influence of strong individual ethical beliefs as measured by the variable moral norm) are direct predictors of intention, separate from attitude and perceived behavioural control.

Based on this theoretical framework, the following hypotheses of consumer adoption of innovations were formulated:

H1. The attitude of dairy consumers towards dairy products applying one of these innovations is positively associated with their intention to buy the product.

H2. The more that a consumer perceives an innovation as beneficial (H2a) or risky (H2b), the more favourable or unfavourable, respectively, is the consumer attitude towards its adoption.

H3. The more a consumer perceives the influence of social and peer pressure to be favourable towards an innovation, the higher the consumer intention towards buying dairy products where the innovation has been applied.

H4. Consumers with higher moral norm are more likely to have higher intention towards buying dairy products that apply the sustainable innovations.

H5. The attitude towards dairy products that apply a sustainable innovation is more favourable for regular organic consumers.

H6. The attitude towards dairy products that apply an innovation is more favourable for female consumers.

Here, H1 and H3 follow directly from the original TPB model. H2 tests the addition of the two antecedents of the variable attitude: (perceived) benefits and risks. H4 tests the relevance of the additional 'norm' variable to explain the intention to buy. The remaining two hypotheses (H5, H6) are postulated to empirically test the role of two socio-demographic variables on the attitudes: organic consumption and gender. Previous studies have reported that organic food consumers have been shown to have environmental sustainability among their core motivations (Zanoli and Naspetti 2002; Schösler et al. 2013), while women are more likely to favour ethical, environmental friendly products than men (among others: Magnusson 2001; Ureña et al. 2008; Ha-Brookshire Jung 2011; López-Mosquera 2016).

Methods

Data collection and operationalisation of the model

The data for the evaluation of the theoretical model were collected through a survey sent out to a panel of 6969 consumers of organic and low-input dairy products. These consumers had been recruited by a sub-contracted computer-aided web interview agency across six European countries: Austria (AT), Belgium (BE), Denmark (DK), Finland (FI), Italy (IT) and the United Kingdom (UK; here as England and Wales).

The survey questionnaire was divided into four sections. The first section was the screening section, which was designed to recruit consumers who drank milk or used other dairy products, who were responsible for the household food purchases and who were not employed (as the consumer or someone else in the consumer's household) in the dairy supply chain (e.g. dairy foods industry or food processing) or in a market research company.

The second section included the description of the novel production practices, of agroforestry, prolonged maternal feeding and alternative protein source. Each of these practices was presented to the respondents in a common format, using statements about strengths and weaknesses, and threats and opportunities related to social, technological, environmental, animal welfare, economic and policy arguments. The specific statements that were shown to the consumers are detailed in the [Appendix](#). After reading these three descriptions, the respondents were asked to rank each of the production practices according to their preferences (1st, 2nd, 3rd).

The third section operationalised the constructs included in the model through 19 itemised questions, to allow estimation of the modified TPB model using confirmatory factor analysis (CFA) and structural equation modelling (SEM). The measures used, their definitions, their reference sources and the scale items are given in [Table 1](#). As indicated above, six constructs were included in the model and questionnaire: perceived risks (3 items; [Bredahl 2001](#); [Tung et al. 2008](#)), perceived benefits (3 items; [Bredahl 2001](#); [Tung et al. 2008](#)), moral norm (3 items; [Bredahl 2001](#); [Dean et al. 2008](#)), subjective norm (3 items; [O'Connor et al. 2006](#); [Dean et al. 2008](#); [Ottar et al. 2008](#); [Tung et al. 2008](#)), perceived behavioural control (3 items; [Bredahl 2001](#); [Saba and Messina 2003](#); [Tung et al. 2008](#)) and attitude towards the production practices (3 items; [Bredahl 2001](#); [Cook and Fairweather 2007](#); [Davis et al. 1992](#); [Tung et al. 2008](#)).

All multi-item constructs were measured using a seven-point Likert scale (from 1, strongly disagree, to 7, strongly agree). One item of the perceived behavioural control construct (v9) was measured using a different seven-point Likert scale (from 1, no control, to 7, complete control).

For parsimony in the administration of the questionnaire, many constructs were just identified; i.e. had only three indicators per latent construct. This is the minimum requirement to identify a CFA model ([Kline 2011](#)). Purchase intention was measured as a single item variable (v19). Only one production strategy was proposed in a randomised order to be evaluated in more detail through the 19 itemised questions; all of the items were also randomised, except the one to measure behavioural intention, which was always presented last.

The fourth section of the survey dealt with socioeconomic information (e.g. gender, age, level of education, net income) and questions to collect data on the respondent knowledge and attitudes towards the purchase of organic dairy products.

Table 1 Definition of the multi-item constructs (original items)

Construct	Definition	Item	Item wording
Perceived risks (Bredahl 2001; Tung et al. 2008)	Risk perceptions associated with the adoption of the production practice in the supply chain	v1	Overall, applying this innovation to dairy production involves considerable risk to the environment, the animals, myself and other people that are important to me.
		v2	Overall, applying this innovation to dairy production will prove harmful to the environment, the animals, myself and other people that are important to me.
		v3	Overall, applying this innovation to dairy production will prove disadvantageous to the environment, the animals, myself and other people that are important to me.
Perceived benefits (Bredahl 2001; Tung et al. 2008)	Benefit perceptions associated with the adoption of the production practice in the supply chain	v4	Overall, applying this innovation to dairy production will prove beneficial to the environment, the animals, myself and other people that are important to me.
		v5	Overall, applying this innovation to dairy production will offer great benefits to the environment, the animals, myself and other people that are important to me.
		v6	Overall, applying this innovation to dairy production will prove advantageous to the environment, the animals, myself and other people that are important to me.
Perceived behavioural control (PBC) (Bredahl 2001; Saba and Messina 2003; Tung et al. 2008)	The perceived ease or difficulty of buying a product from farms applying the production practice	v7	If dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding] were available in the stores nothing would deter me from buying them.
		v8	Whether I would buy dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding]—if available in the stores—is entirely up to me.
		v9	How much control do you believe you have over whether or not you purchase dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding] for your household if available in the stores?
Moral norm (MN) (Bredahl 2001; Dean et al. 2008)	A consumer's personal beliefs regarding what is right or wrong	v10	Buying dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding] feels like the morally right thing to do.
		v11 (R)	Buying dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding] goes

Table 1 Definition of the multi-item constructs (original items) (*Continued*)

Construct	Definition	Item	Item wording
			against my basic principles.
		v12	Buying dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding] would make me feel like a better person.
Subjective norm (SN) (Dean et al. 2008; O'Connor et al. 2006; Olsen et al. 2008; Tung et al. 2008)	A consumer's perception of relevant opinions on whether to purchase a dairy product from farms applying the production practice	v13	Most people who are important to me would approve of me buying dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding].
		v14	Most people who I value think that I should buy dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding] if they were available in the shops.
		v15	My family would encourage me to buy dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; C. prolonging maternal feeding].
Attitude (ATU) (Bredahl 2001; Cook and Fairweather 2007; Davis et al. 1992; Tung et al. 2008)	Consumer positive or negative feeling associated with the adoption of the production practice	v16	The introduction of such innovation in the supply chain would be acceptable for me.
		v17	All things considered introducing such an innovation in the dairy supply chain is not a good idea.
		v18	Applying such an innovation in the dairy supply chain would be wise.
Intention to purchase (Venkatesh et al. 2003)	Consumer intention to purchase a dairy product from farms applying the production practice	v19	All things considered, if dairy products produced on farms utilizing [A. agroforestry; B. alternative protein sources; c. prolonging maternal feeding] were available in the shops, I would definitely buy them.

(R) reverse ranking

The questionnaire used in the survey was written in English and translated into the other languages by mother-tongue researchers. Back-translation was used to check that the original sense of each question was not lost in the translations. Extensive cross-checking, editing and pre-testing was conducted before administering the survey. After data collection, eligibility and consistency checks were performed, and 5497 consumer responses were retained.

The eligibility criteria for the sample were the following:

- Being responsible for the family food shopping
- Not being employed (the consumer or someone else in the consumer's household) in one of the following professions: dairy food industry or food processing, or a market research company

- Buying milk and other dairy products for personal consumption and/or for other members of the consumer's household

According to these criteria, 778 respondents were deemed ineligible. Also, 668 'speeders' were excluded from the final sample (i.e. those who used less than 4.5 min to complete the survey).

Data analysis

Estimation of the CFA and SEM models was performed using a robust (Satorra-Bentler) maximum likelihood estimator (Satorra and Bentler 1994; Hancock and Mueller 2013) using Mplus 8 (Muthén and Muthén 2017). We conducted a post hoc analysis to perform further model invariance tests finalised to latent means difference testing:

- Across non-organic, occasional and regular organic consumers (levels of organic experience)
- Across genders (male vs. female)

In addition, latent means difference tests were carried out to check whether for each alternative production practice there were different mean attitudes across countries.

Results

Sample socio-demographics

The majority of the respondents included (i.e. consumers) had attained secondary education, with some differences across the countries. A comparison with Eurostat (2014a) data showed that the consumers with tertiary education were over-represented in this sample, which was particularly evident for Belgium and Italy¹. The full sample description is given in Table 2.

The majority of the consumers' households in the overall samples (59%) had a net income below the official average monthly wage for the selected countries (about 2366 euros per month). The median wage was 1500–2500 euros per month. According to the country means, 32.8% of households received on average 2269 euros per month, with Italy as the lowest (1983 euros per month; standard deviation 0.9) and Denmark the highest (2619 euros per month; standard deviation 1.1). The inequality in income distribution was measured by the Gini index (Fig. 2). These data showed that the household monthly net income distribution for this sample was a little lower than the official statistics from Eurostat (2014b).

The mean number of people in each of the consumers' households was a little over two, with the exception of Italy, which exceeded three people. The majority of these households were made up of couples (36.7%).

With respect to the consumer experience with organic products, as measured by the proxy variable 'self-reported frequency of purchase', they were divided into three groups: non-organic consumers (consuming organic products less than once per month), occasional organic consumers (consuming organic products at least once or

¹For the mean of the five countries studied, Eurostat (2014a) reports the following educational attainment levels: less than secondary education, 25.7%; secondary education, 45.1%; and tertiary education, 29.3%.

twice per month) and regular organic consumers (consuming organic products once or more per week). Organic self-reported regular consumers represented about one third of the overall sample, occasional consumers one fourth, and the remaining 43% were non-organic consumers.

Evaluation of the measurement model and assessment of cross-culture validity

Cross-culture validity refers to the measurement invariance across the different nation groups and reflects 'the extent to which the data collected by the same measurement instrument are comparable across different cultural environments' (Bredahl 2001).

Confirmatory factor analysis was conducted on multi-item scales for each practice across each country, such as attitude, subjective norm, moral norm, perceived behavioural control, perceived benefits and perceived risks. Given that the multi-item latent variables were measured by ordered categorical indicators, inspection of the data suggested a robust estimation method for departure from normality. Following Finney and Di Stefano (in Hancock and Mueller 2013), we used Satorra-Bentler scaling of the variables with maximum likelihood estimation.

Estimation of the CFA models for each practice and cross-country validation resulted in the exclusion of perceived risks and perceived behavioural control from the final measurement model (they also showed poor reliability; i.e. Cronbach's alpha < 0.63; King and He 2006). The following items were also excluded from the analysis: v11 (in moral norm) and v13 (in subjective norm). All of the measurement statistics for each novel production strategy are given in Table 3, 4 and 5, while the tests of the validity of the CFA models are given in Table 6.

^aThe latent variable covariance matrix is not positive definite

^bConstructs not included in the final measurement model

These results were not surprising. Perceived behavioural control is rarely significant in most of the reviewed literature. The exclusion of perceived risks from the final measurement model was also not unexpected, as consumers do not perceive any significant risks should the farmers adopt any of the tested practices.

Tables 7, 8 and 9 report the results of the measurement invariance tests for each production practice. Multiple-sample CFA were run across the various countries: chi-square difference tests are reported for configural vs. metric and metric vs. scalar measurement invariance. These invariance tests are affected by the overall sample size (very large here), which led to rejection of the invariance in most cases. Therefore, following Cheung and Rensvold (2002) and Meade et al. (2008), we also report the Bentler Comparative Fit Index (CFI): changes in CFI (ΔCFI) ≤ 0.01 indicate that the null hypothesis

Table 7 Tests of cross-country measurement invariance—agroforestry

Model	χ^2	DF	Correction factor	Corrected χ^2	P value	CFI	Δ CFI
Configural (C)	261.490	162	1.513			0.987	
Metric (M)	307.056	192	1.475			0.985	0.002
Scalar (S)	476.698	222	1.413			0.966	0.019
Diff. C vs M	45.116	30	1.270	45.104	0.038		
Diff. M vs S	218.114	30	1.016	217.149	0.000		

of invariance should not be rejected. Agroforestry showed metric invariance, meaning that there were equal factor loadings across countries. Both prolonged maternal feeding and alternative protein source, on the other hand, showed the stronger form of cross-cultural validity (scalar invariance), which means that the factor loadings and intercepts/thresholds were equal across the countries.

Convergent validity is supported by the high and significant standardised loadings for the measures (Anderson and Gerbing 1988). Multiple-group measurement invariance was also tested for two relevant socio-demographic variables, experience (non-organic vs. occasional and regular consumers) and gender (male vs. female), to determine whether differences in the latent means could be explored for these cases. Again, exploration of the Δ CFI indicated that neither the null hypotheses of metric nor scalar invariance should be rejected (results not shown).

Finally, measurement invariance was also tested for the pooled country data across the three production practices, to determine whether it was possible to proceed to test a pooled structural equation model across both countries and innovations. As metric invariance was not rejected for all of the production practices, we can report the results of the pooled CFA models (covering AT, BE, DK, FI, IT, UK), all of which showed close fits (Table 10). In the pooled CFA models, all of the loadings of variables were significant and above the 0.50 threshold.

Ranking of innovative production strategies

Respondents were asked to read a brief description of each of the novel production strategies and then to rank these in their order of preference according to their personal point of view. Figures 3, 4 and 5 report the country differences for each novel production strategy. These pooled results show that the production strategy ‘prolonged maternal feeding’ was ranked first by 42.1% of the consumers and second by 31.8%, for a total of 73.7%. ‘Agroforestry’ was a little less favoured, as it was ranked first by a third of the consumers (33.3%) and was ranked second by another 38.2%, for a total of

Table 8 Tests of cross-country measurement invariance—prolonged maternal feeding

Diff. M vs S	111.744	30	1.002	137.107	0.000		

71.5%. Although there were differences across the countries, ‘alternative protein source’ was the least preferred strategy by the respondents: only 24.6% of them ranked it first.

Attitude towards behaviour and intention to purchase

The consumer attitude towards adopting dairy food products from farms that used each of the alternative production practices was measured according to the three items described above and given in Table 1. By inspecting the mean ratings (Table 11) for all of the countries taken together, we can conclude that *attitude towards behaviour* was significantly higher for dairy products produced using prolonged maternal feeding than for agroforestry, while the practice of alternative protein source had a significantly lower mean rating than these other two.

The intention to purchase products that were produced using these three practices was measured according to a single seven-point bipolar item (i.e. extremely likely to extremely unlikely). As shown in Figs. 6, 7 and 8, for all three of the practices, the modal category was ‘somewhat likely’ (i.e. a value of 5 in the Likert scale adopted), although for alternative protein sources the category ‘neither likely nor unlikely’ was chosen with almost the same frequency (Fig. 8).

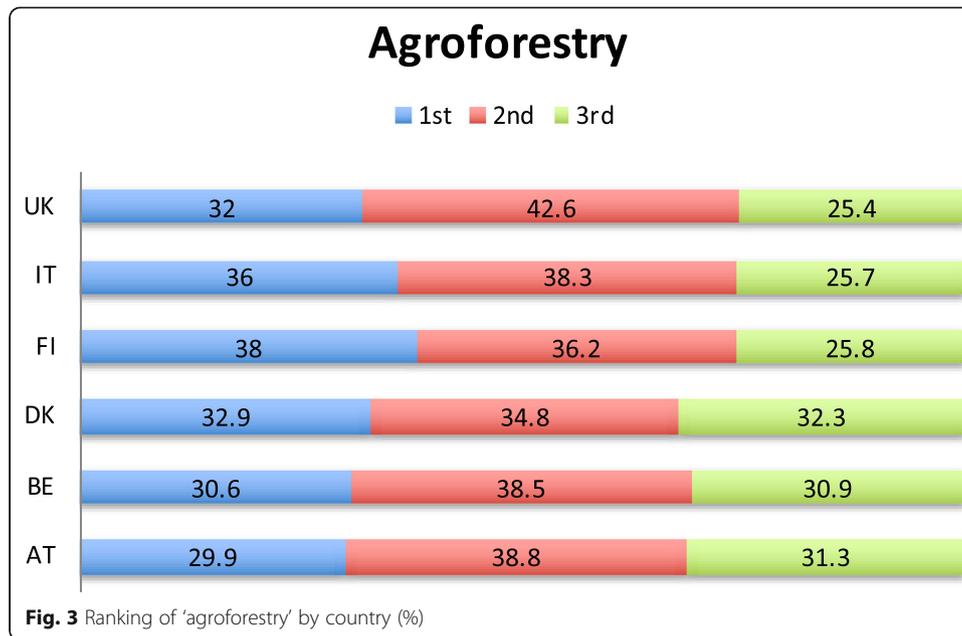

Through inspection of the mean ratings for all of the countries taken together (Table 12), we can conclude that *intention to purchase* was a little higher for dairy products produced using agroforestry than prolonged maternal feeding. Consistent with the overall observed pattern of rankings, the practice of alternative protein source had the lowest mean rating here, and it followed a more skewed distribution.

Results of the structural equation model

For the analysis of the structural equation model, the full sample of consumers was used (i.e. 5497 complete responses). Each consumer rated only one single practice. As these data showed measurement invariance, we could proceed by estimating one pooled cross-country model for each alternative production practice. The estimated structural equation models for each alternative production practice are presented in

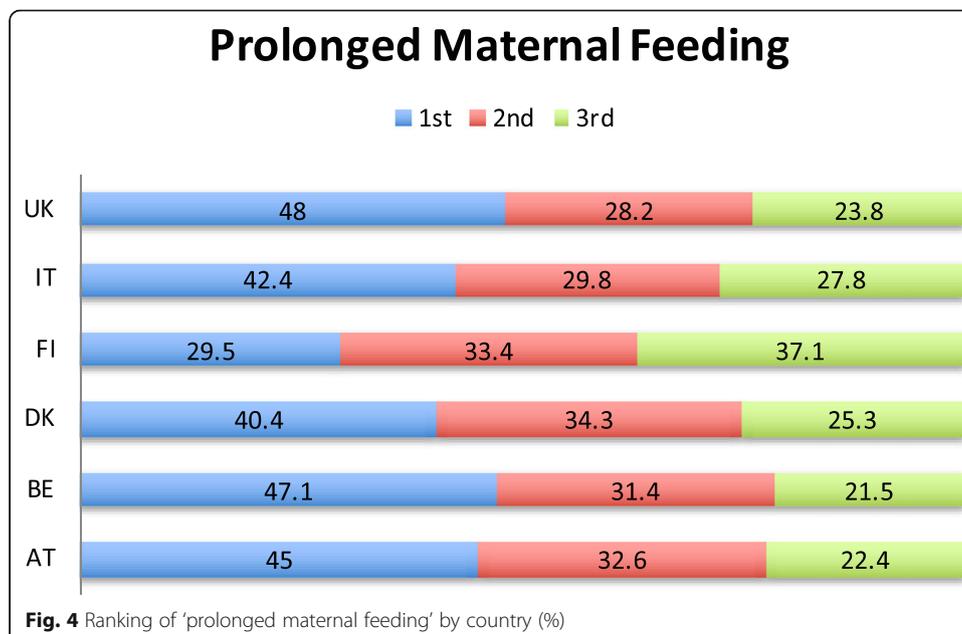

Table 10 Pooled confirmatory factor analysis model fit indices

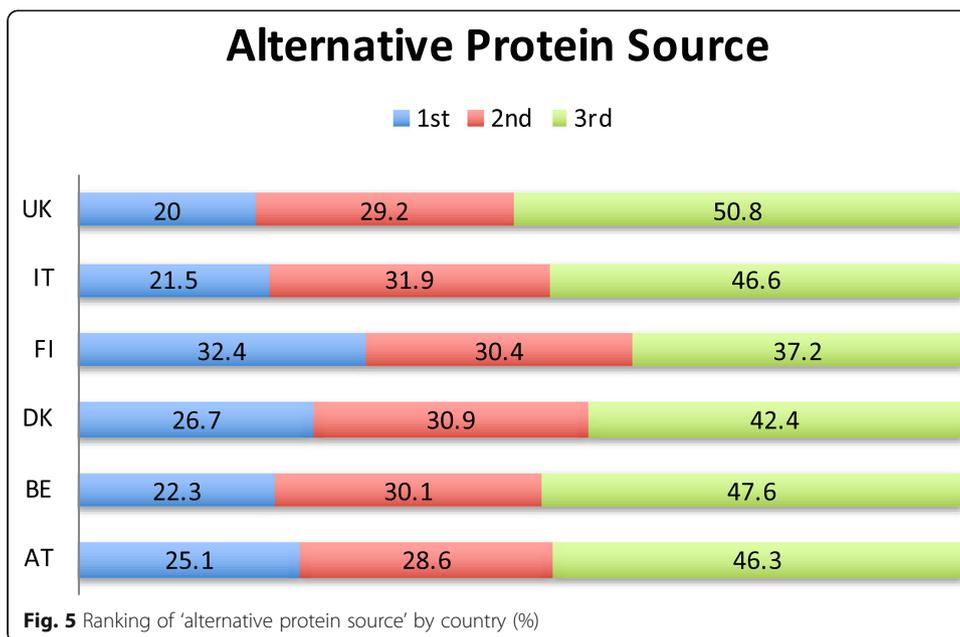

Model	χ^2	df	P value	RMSEA			SRMS R	CFI
				Value	90% CI	Probability (≤ 0.05)		
Agroforestry	90.74	27	< 0.001	0.036	0.28–0.44	0.998	0.021	0.992
Prolonged maternal feeding	114.10	27	< 0.001	0.042	0.34–0.05	0.948	0.023	0.988
Alternative protein source	86.74	27	< 0.001	0.035	0.27–0.43	0.999	0.020	0.992

Figs. 6, 7 and 8. All three of the models showed close fits with the observed data, as reported in Table 13.

Inspection of the models made it clear that while the three production practices shared an invariant measurement part, they had a non-invariant structural part that distinguished each practice from each of the others in terms of how the consumer attitudes and purchase intentions were formed. First of all, in the agroforestry model, the path moral norm to intention to purchase was not significant (and therefore could be deleted). Intention is explained by attitude and, to a lower extent, by subjective norm. This was specific to agroforestry, as the other two production practices appeared to have a more similar structural part in both the formation of consumer attitude towards

the proposed production practices and in the formation of the intention to purchase. In all cases, perceived benefits were highly correlated with attitude, which in turn was the most relevant factor that influenced intention to purchase for all of the practices except for alternative protein sources. For this last innovative practice, consumer attitude was much lower, and it basically had the same influence on intention to buy as moral norm. Moral norm appeared to be a more relevant antecedent of intention to purchase than subjective norm if agroforestry was excluded, where it was not a significant predictor of intention, as previously shown (Figs. 9, 10 and 11).

Post hoc analysis

Full metric invariance held across both levels of organic experience and gender and across countries. Therefore, we proceeded in the testing for latent means differences in attitude.

Table 14 gives the results for the means difference testing of attitude towards each of these innovative production practices across gender and levels of experience. The results in terms of attitude towards the three alternative innovative production practices show that females are more favourable (i.e. exhibit higher values for attitude) than men. Organic consumers (both regular and occasional) are more favourable than non-organic consumers. These results will be discussed in details below, in relation to their respective hypotheses.

Table 11 Descriptive statistics for attitude towards behaviour (all countries)

Model	Mean	Standard deviation
Agroforestry	4.73 ^a	1.08
Prolonged maternal feeding	4.83 ^b	0.99
Alternative protein sources	4.36 ^c	1.06

Values with different superscript letters are significantly different ($p > 0.01$; Bonferroni adjusted)

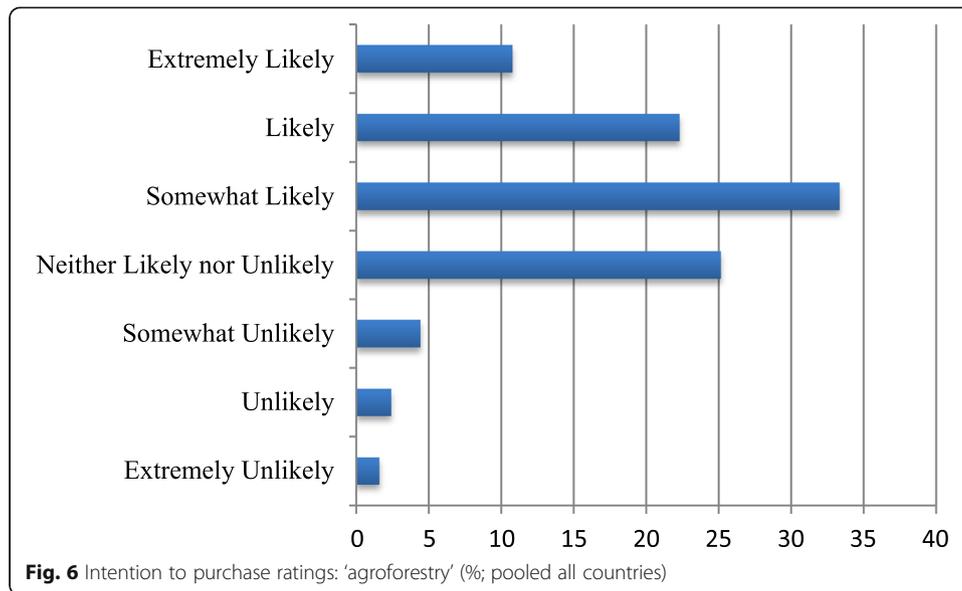

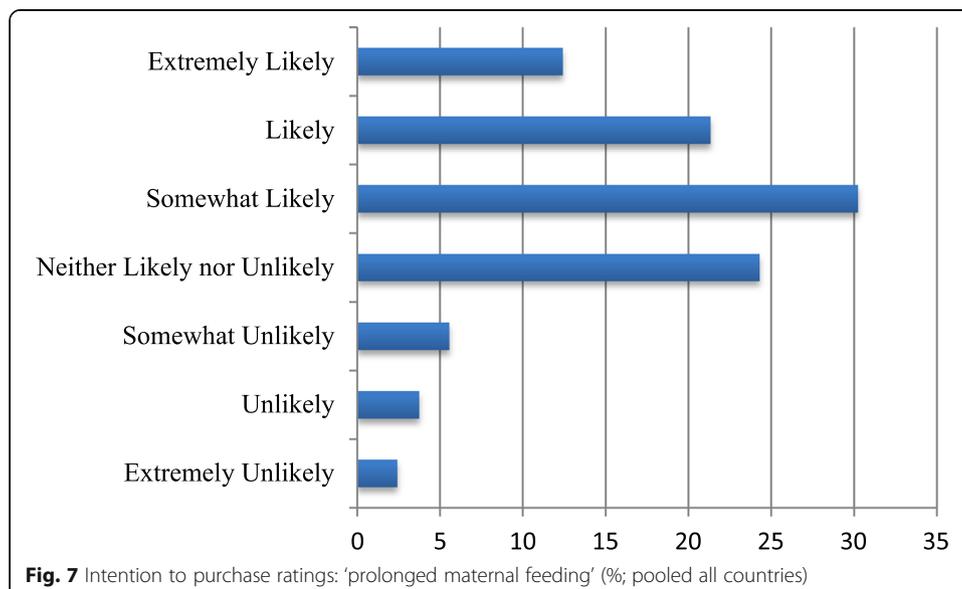

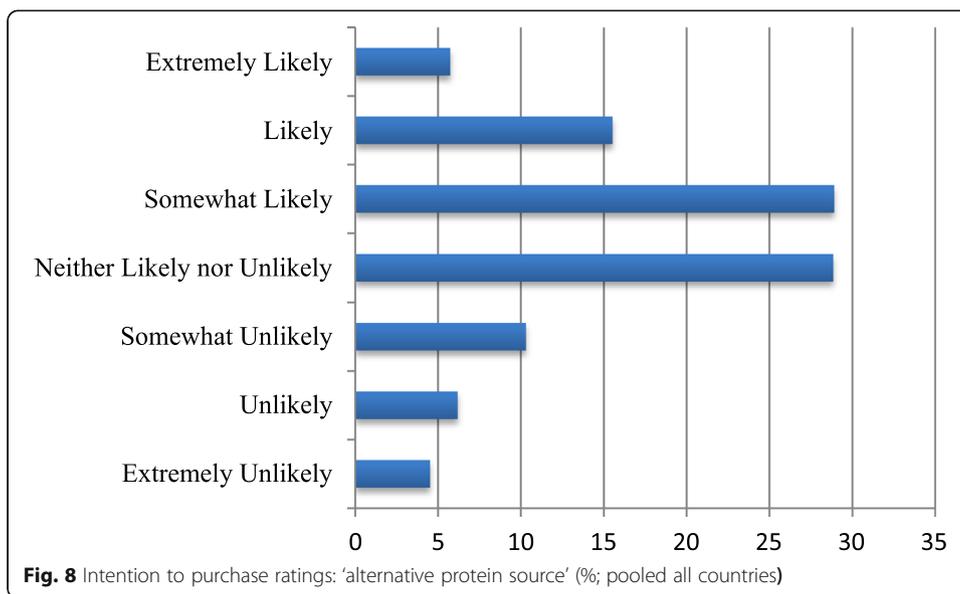

Table 15 gives the results for the means difference testing of attitude towards each of these innovative production practices across the countries. The results show that there are not many differences among these countries in terms of attitude towards the three alternative innovative production practices.

Table 15 gives the results for the means difference testing of attitude towards each of these innovative production practices across the countries. The results show that there are not many differences among these countries in terms of attitude towards the three alternative innovative production practices. The only statistically significant differences were the following:

- Finnish consumers appear much less favourable than all of the others to prolonged maternal feeding, followed by the UK consumers.

- Italian consumers were more favourable than all of the others to agroforestry, followed by the Finnish consumers. All of the consumers in the other countries do not differ in terms of their attitude towards agroforestry.
- There were no country differences in terms of consumer attitudes towards alternative protein sources.

These country variations are expected, but we can conclude that attitudes are, overall, relatively homogenous across Europe.

Discussion

Explanatory power and testing of the hypotheses

The models provided good insights into the formation of attitudes and purchase intentions towards dairy products obtained using these three production practices.

Hypothesis 1 was clearly supported. As we were simply measuring the attitudes towards these practices, this finding confirms the strength of the Bredahl (2001) and Chen (2008) purchase intention models.

Hypothesis 2 was partially supported, in the sense that perceived benefits appear to be strongly driving attitude, while given the nature of the proposed technological improvements, perceived risks did not have any role in our model.

Hypothesis 3 was supported, where the role of subjective norm in influencing intentions was confirmed for all of the production practices.

Table 12 Descriptive statistics for intention to purchase ratings (all countries)

Model	Mean	Standard deviation
Agroforestry	5.0 ^a	1.2
Prolonged maternal feeding	4.9 ^a	1.4
Alternative protein sources	4.4 ^b	1.4

Values with different superscript letters are significantly different ($p > 0.01$; Bonferroni adjusted)

Table 13 Pooled SEM model fit indices

Model	χ^2	df	P value	RMSEA			SRMS R	CFI
				Value	90% CI	Probability (≤ 0.05)		
Agroforestry	131.70	36	< 0.001	0.038	0.31–0.45	0.997	0.023	0.988
Prolonged maternal feeding	127.72	36	< 0.001	0.037	0.30–0.44	0.999	0.021	0.990
Alternative protein source	121.34	36	< 0.001	0.036	0.29–0.48	0.999	0.020	0.990

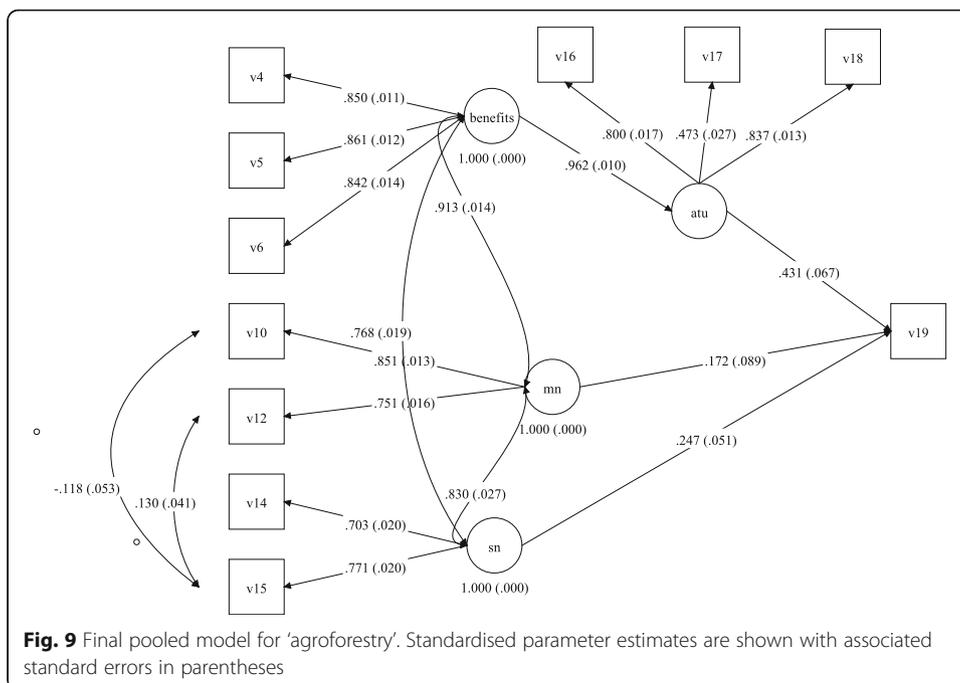

Hypothesis 4 referred to the relevance of moral norm as an antecedent of intention to purchase, and it was supported for two of the innovative production practices out of three.

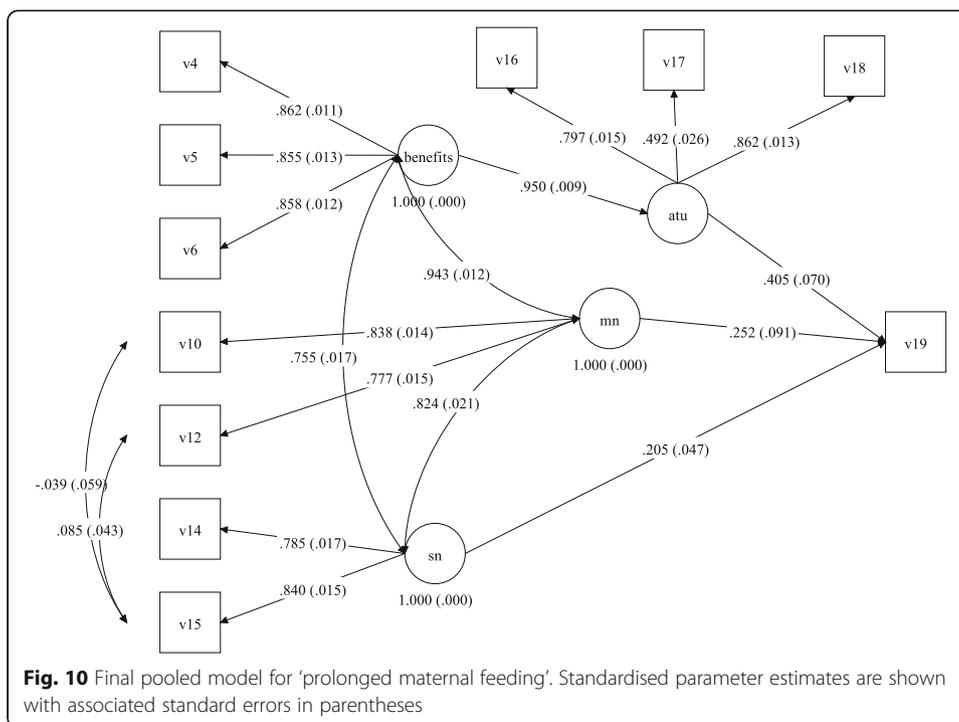

The results of post hoc analysis allow the testing of Hypotheses 5 and 6.

Regarding the former (hypothesis 5), occasional organic consumers appeared to have a more favourable attitude towards all of these innovations than non-organic consumers, while regular consumers were even more favourable (i.e. exhibited a higher mean difference). One significant exception was for alternative protein source, where regular consumers showed a lower positive attitude than occasional consumers. All of the differences in the means and standardised effects sizes (differences standardised in terms of standard deviation) were significant ($p < 0.01$).

We can conclude here that occasional organic consumers are, on average, about 0.24 of a standard deviation greater than non-consumers in terms of favourable attitude towards agroforestry, 0.18 of a standard deviation greater than non-consumers in terms of favourable attitude towards prolonged maternal feeding and 0.35 of a standard deviation greater than non-consumers in terms of favourable attitude towards alternative protein source.

Regular consumers were, on average, about 0.28 of a standard deviation greater than non-consumers in terms of favourable attitude towards agroforestry, 0.37 of a standard deviation greater than non-consumers in terms of favourable attitude towards

prolonged maternal feeding and 0.24 of a standard deviation greater than non-consumers in terms of favourable attitude towards alternative protein source.

Hypothesis 5 was also not rejected. Together with hypothesis 4, this allowed us to conclude that the more value-driven consumers are, the more favourable they are towards these sustainable production practices.

For hypothesis 6, these data also favour a highly significant difference between women and men in terms of attitude towards all of the practices except alternative protein source. Women were, on average, 0.19 of a standard deviation greater than men in terms of favourable attitude towards agroforestry and 0.17 of a standard deviation greater than men in terms of favourable attitude towards prolonged maternal feeding.

Conclusions

This study examined how a number of socio-psychological constructs and personal characteristics affect consumer attitudes and intentions towards dairy products obtained through using three innovative and sustainable production practices: agroforestry, prolonged maternal feeding and alternative protein sources. Across all of these countries, prolonged maternal feeding was the production practice that showed the highest level of acceptance by consumers. The least accepted practice was alternative protein source for the feeding of dairy cows.

The following conclusions can be drawn from these data:

1. Prolonged maternal feeding was the most accepted practice by consumers. This strategy would clearly increase the production cost for dairy farmers by limiting the milk that is available for sale. Therefore, it might be a viable solution only if the farmers received adequate monetary compensation for potential losses. Further

investigations into the willingness-to-pay associated to these practices are needed, although this is beyond the scope of the present study.

- Alternative protein source appears not to be fully understood by consumers as a practice that might be of benefit to them. Indeed, consumer knowledge of the animal production process is very basic (Frewer et al. 2005; McEachern and Seaman 2005; Di Pasquale et al. 2014), and therefore, this result is not particularly surprising. One explanation might be that the consumers perceived the innovative practice as mainly of benefit to the farmers, as they might not have fully understood the importance in terms of food safety and traceability of reducing the outsourcing of protein by farmers.
- Agroforestry appears to be of low interest for consumers. As a practice, it has different acceptance in different countries, given the differences in their dairy systems. If coupled with an approach that increases grazing and, more generally, favours grass-fed dairy systems, agroforestry might be an important practice that would appeal to both consumers and policymakers. It might also help in the pursuing of other societal goals (e.g. low-carbon sustainable production, use of forage that does not compete with human food production). Further investigation into the acceptance by other supply chain members is needed.

As a general conclusion, this study has shown that sustainable dairy farming practices that are not perceived as addressing relevant ethical concerns or producing easily perceivable societal benefits are not likely to be accepted by consumers. Given that organic dairy products are well accepted by consumers, who are ready to pay more for them, the proposed innovations are likely to be relevant only if they become part of organic best practices.

A number of potential limitations can be identified here. First, this study was focussed on behavioural intention, rather than actual or hypothetical choice of products that were produced using the identified practices. While intention is a necessary condition, it is not a sufficient condition for actual consumer choice. Furthermore, actual choice implies not only acceptance, but also evaluation of consumer perceived costs to counter the benefits of the proposed innovations. A study on actual or hypothetical choice implies a different design and is left for future research.

Appendix

Information presented on the alternative production practices:

1. Agroforestry
 - (a) Integration of animals (i.e. cows, sheep) and trees on the same plot of land
 - (b) Innovation strengths/opportunities:
 - I. Enables production of wood, forage, livestock and fruit or nuts (depending on trees chosen) on the same plot of land, which improves farm revenue
 - II. Increases soil and plant biodiversity and carbon sequestration and reduces soil erosion
 - III. Trees offer shelter to grazing animals, which benefits animal welfare
 - (c) Innovation weaknesses/threats:
 - I. High initial financial investment for the purchase of trees and ongoing management input
 - II. Forage value of the leaves for animal nutrition is largely unknown.
 - III. Trees may be damaged by livestock that eat, step on or rub against them.
2. Prolonged maternal feeding
 - (a) Calves and lambs can suckle directly from their mothers (or a foster mother) for the first 3–5 months after they are born.
 - (b) Innovation strength/opportunities:
 - I. Maternal feeding provides natural immunity for the animals
 - II. Improvement in animal welfare, as animals are allowed to exhibit natural behaviour
 - III. Additional costs of buying milk replacer to feed the calves/lambs can be avoided.
 - (c) Innovation weaknesses/threats:
 - I. Provision is needed for changes in the housing/handling of both the mother and the offspring.
 - II. Separation causes mother and offspring stress as they have had time to develop a strong social bond.
 - III. Reduction in the amount of milk available to sell commercially during the calf/lamb suckling period
3. Alternative protein source
 - (a) Use of home-grown protein crops, such as lupins, beans and peas, as animal feed
 - (b) Innovation strength/opportunities:

- I. Reduces the amount of imported soya from outside the EU and therefore reduces the risk of contamination of the European food chain by genetically modified organisms
 - II. Cultivation of protein crops, such as field beans and peas, has a fundamental role in organic/low-input agriculture by improving soil fertility.
 - III. Farmers can produce animal feed on the farm and therefore avoid extra costs associated with third party supplies, logistics, delivery and handling.
- (c) Innovation weaknesses/threats:
- I. Limited research available to determine the effects of alternative proteins on dairy animal production and long-term impact on health and fertility
 - II. Protein content and biological value of local alternative protein crops are often lower than for soya.
 - III. Locally home-grown alternative proteins might be insufficient to fulfil year round demand of dairy farms, and therefore feed from external sources might still be required.
